NH₃ production is a process of high scientific and technological interest due to its wide range of applications, such as fertilizers and fuels. Electrochemical nitrate reduction (NO₃RR) emerges as a promising alternative to the Haber-Bosch process,¹ as the energy required can be supplied in the form of electricity and produced by renewable sources. Cobalt/Copper-based dual site electrocatalysts have shown promising results for NO₃RR, such as high efficiency, selectivity and stability.² Herein, we developed a Co₃O₄/Cu_xO_y electrocatalyst and activated it by different pre-treatments, enhancing the selectivity for NH₃ production. SEM/EDX revealed Cu_xO_y porous agglomerates (1.7 to 3.2 μm) and Co₃O₄ nanowires (~0.4 μm diameter) homogeneously distributed over the catalyst surface. XRD patterns identified the presence of Cu₂O and Co₃O₄ cubic phases and planes of monoclinic CuO. The electroactivity was evaluated by slow CV of 1 mV s⁻¹, which shows the onset for NO₃RR at 0.20 V_{RHE} and a multi-step reaction to NH₃. Aiming to boost nitrate-to-NH₃ efficiency, two electrochemical surface activation protocols were applied: i) 10 CV cycles from 0.15 to -0.40 V_{RHE} at 20 mV s⁻¹ (CV-activated) and 1-h chronoamperometry at -0.30 V_{RHE} (CA-activated). At -0.2 V_{RHE}, CA-activated enhanced the FE (and YR) of NH₃ to 94.4 ± 3.1% V_{RHE} (43.4 ± 3.2 μmol h⁻¹ cm⁻²) vs. 38.8 ± 6.9% (26.8 ± 9.2 μmol h⁻¹ cm⁻²) of the CV-activated. Surface (XPS) and structural characterization (*in situ* XAS) suggest that the increased performance and selectivity is due to the formation of Cu⁰/Cu⁺ and Co₃O₄/Co(OH)₂ active sites favored by the chronoamperometric pre-treatment. The dissolution process during electrochemical activation was evaluated by *on line* ICP-MS. Overall, the dissolution of Cu and Co in negative potentials were observed, however, much less pronounced in CA-activated method which clearly indicates the preservation of the active sites. Identification of the reaction intermediates was assessed by *in situ* FTIR and *on line* DEMS, converging to the idea that NH₃ was mainly formed by sequential hydrogenation of NO instead of the decomposition of hydroxylamine.
